

ACCESSION NR: AP4020316

difference between two voltages within the same range. The device (see Enclosure 1) comprises: a balanced differential amplifier, T₁ T₂ T₃; two amplifier-inverters, T₄ T₅; two separating amplifier-inverters, T₆ T₇; two comparator diodes with blocking oscillators, D₁ D₂ T₈ T₉; two output pulsed forming amplifiers (damping diodes D₃ D₄, transistors T₁₀ T₁₁). P403 transistors are used in the blocking oscillators, P13 transistors in all other places; diodes are silicon D106. The device is essentially a dynamic polarity recorder; a "static trigger" is necessary for the "static recording" of polarity.

TITLE: Investigating the process of chemical reduction for the preparation
of high-dispersed silver powder

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 4, 1962, 42, abstract 4G274
("Poroshk. metallurgiya", 1961, no. 5, 53 - 59, English summary)

TEXT: The authors studied the chemical reduction process of a AgNO_3 solu-
tion with FeSO_4 solution. To obtain high-dispersed Ag powder (80% of $1 - 5 \mu$
fraction) the AgNO_3 concentration should be 0.1 M, and FeSO_4 concentration as
high as 0.2 M. The necessity of thorough filtration of the solutions is noted.
The authors studied washing and drying conditions and the properties of the pow-
der obtained (dispersity and chemical activity). Clodding of the powder can be
prevented by adding protective colloides to the solution.

TITLE: Production of highly dispersed silver powders

PERIODICAL: Poroshkovaya metallurgiya, no. 2 1962, 49-57

TEXT: Various aspects of production technology of highly dispersed light colored powders are discussed in connection with the silver coating process of watch dials, developed in the Soviet Union in 1959. The size of the silver particles should be $2-3\mu$, this particle size comprising not less than 85% of the total amount of powder. The electrolysis was carried out in a 250 ml round glass container using 99.9% silver anodes and a polished stainless steel cathode. The anode to cathode surface ratio was 3-5 : 1. The authors investigated the influence of the concentration and cathodic current on the physical properties of the powders. Lower concentrations give more highly dispersed and uniform powder, while increasing cathodic current results in a finer but darker material. The beneficial influence of surface-active brightening agents on the dispersity and homogeneity of the powders is stressed. There are 4 figures and 5 tables.

TOPIC TAGS: clay refractory product, refractory product, fire clay

ABSTRACT: The effects of degree of alumina pulverization, the clay composition, the proportion of clay to alumina, and the firing temperature on the properties of fire clay were investigated. This investigation supplements the results of D. S. Rutman and L. V. Vinogradova (Ogneupory, 1954, No. 3, 105--113). Fire clay specimens were prepared from different initial alumina-clay fractions, extending from 90 to 30% alumina, and were fired at three different temperatures—1330, 1410, and 1520°C. The apparent porosity, shrinkage, homogeneity, and water-carrying capacity of the specimens were determined. The experimental results are summarized in graphs and tables (see Fig. 1). It was found that best results were obtained for a ratio of 90% fire clay, particle size < 0.09 mm, and 10% clay (80% alumina + 20% clay),

AUTHOR: Yudina, A. S. (Moscow)

TITLE: Cylindrical functions of two variables

SOURCE: Zhurnal vychislitel'noy matematiki i matematicheskoy fiziki, v. 4, no. 2, 1964, 222-231

TOPIC TAGS: cylindrical function, asymptotic expansion, contour integral, telegraph equation, two variable cylindrical function

ABSTRACT: Cylindrical functions of two variables arise in the following contour integral of mathematical physics:

$$\frac{1}{2\pi i} \int F(u, R) \exp \left[\frac{s_1}{2} (au + b + R) \right] du,$$

where $F(u, R)$ is a rational function of u and

$$R = \sqrt{Au^2 + Bu + C}$$

Card 1/3

ACCESSION NR: APL4024556

z_1 is a parameter, a, b, A, B, C are constants, and γ is a closed contour containing all of the singularities of the integrand. The cylindrical functions are classified. The cases of real, imaginary, and complex arguments are considered and various recurrence relations are obtained. The asymptotic expansions of $\theta_n(cx, x)$ and $V_n(cx, x)$ are investigated where

$$\boxed{V_n(w, z) = \sum_{m=0}^{\infty} (-1)^m \left(\frac{z}{w}\right)^{n+2m} J_{n+2m}(z),}$$
$$\boxed{\theta_n(w, z) = \sum_{m=0}^{\infty} (-1)^m \left(\frac{z}{w}\right)^{n+2m} J_{n+2m}(z) = i^n V_n(iw, iz).}$$

Results for the case of c real were previously obtained by P. I. Kuznetsov and A. S. Yudina. It is shown that under certain conditions these results remain valid for complex values of c . As an application, the solution of a system of telegraphic equations is considered. Solutions are given for various boundary conditions. Depending on the boundary conditions, all classes of cylindrical functions

Card 2/3

1975-10-10 100-1010

On page 173 there are two formulas:
 $\phi_{\alpha}(x) = \frac{1}{2} \left(\phi_{\alpha}(x_1) + \phi_{\alpha}(x_2) \right)$ This is true if and only if
the two numbers x_1, x_2 have different signs. One of the possible ways to
prove this is to begin by writing down the
formulas for $\phi_{\alpha}(x_1)$ and $\phi_{\alpha}(x_2)$. The result is that
 $\phi_{\alpha}(x_1) + \phi_{\alpha}(x_2) = \phi_{\alpha}(x_1 + x_2)$. Then it is necessary to prove
that $x_1 + x_2 \neq 0$. It is an easy task to
show that every two zeros of $\phi_{\alpha}(x)$ are
separated by at least 10 steps. If $x_1 + x_2$ were
zero it exists at most one zero of $\phi_{\alpha}(x)$. So we
find that $\phi_{\alpha}(x_1)$ and $\phi_{\alpha}(x_2)$ cannot both be
zero. On every two zeros of $\phi_{\alpha}(x)$ there is
at least one zero of $\phi'_{\alpha}(x)$. The problem
now is that one zero of $\phi'_{\alpha}(x)$ can be obtained
 $\phi_{\alpha}(x_1)$ and $\phi_{\alpha}(x_2)$ cannot have two adjacent zeros.
He thanks to P.I. Kugnetsov for advice. On 9. 10. 75.

formulas: $\phi_{\alpha}(x_1) = \phi_{\alpha}(x_2) = 0$, $\phi'_{\alpha}(x_1) = \phi'_{\alpha}(x_2) = 0$

TITLE: Methods for determining autoignition temperatures of oil

SOURCE: Metody otsenki ekspluatatsionnykh svoystv reaktivnykh topliv i smazochnykh materialov (Methods for the performance evaluation of jet propellants and lubricants). Moscow, Izd-vo Mashinostroyeniye, 1966, 126-130

TOPIC TAGS: autoignition, temperature measurement, lubricating oil, thermocouple, test method

ABSTRACT: The authors discuss the results of a comparative study of three general methods used for determining the autoignition temperatures of aviation oil. The object of the study is to select the most efficient method. The three methods studied are the Yench method, the "drop" method and a method developed by the Scientific Research Institute of the Civil Air Fleet. The Yench method is characterized by the fact that autoignition temperature is determined at a constant oil-to-air ratio without the necessity for considering oil type. A description is given for the apparatus used in the Yench method. This equipment consists of an electric furnace with an ignition crucible in the form of a large metallic cylinder with four chambers. Three of these

Card 1/3

UDC: 662.753.32:629.13.001.4

L 02399-67

ACC NR: AT6015205

chambers contain cups made from stainless steel and the fourth chamber contains a thermocouple. All chambers are connected by an air or oxygen channel. After energizing the electric furnace, the oil to be tested is fed into the cups at 5° intervals starting 100°C below the assumed autoignition temperature. Air is simultaneously introduced at a rate of 100 cm³/min and the point of ignition is recorded. The lowest temperature at which ignition takes place is assumed to be the autoignition point. The experiment is repeated several times to ensure accuracy. The "drop" method is characterized by the fact that the quantity of oil has to be considered before the experiment. This is done by starting with an oil-air mixture with the lowest autoignition temperature for the given oil. The apparatus used for this method consists of a quartz beaker located in a slotted electric furnace made from cast steel with a ceramic covering and annular channels for the heating coil. The top of the beaker has two openings — one for introducing drops of oil and the other for a thermocouple. The electric furnace is heated to 100-150°C above the expected autoignition temperature and oil is introduced into the reaction zone as the furnace is cooled. Ignition is observed through a vertical slot. The apparatus of the Scientific Research Institute of the Civil Air Fleet consists of a plate made from stainless refractory steel 3-4 mm thick located on an electric plate and covered by a double jacket. The air space within the double jacket acts as insulation. This method provides simultaneous measurements of the gas phase temperature at a given distance from the plate by using a thermometer, and the metal plate temperature by using a thermocouple. The metal plate is heated to 20-50°C above the expected autoignition temperature and cooled as

Card 2/3

L 02399-67

ACC NR: AT6015205

0.2 cm³ doses of oil are added at 5° intervals through a special opening. The auto-ignition point is established as the 5° interval which does not produce autoignition. A comparison of the methods shows that the "drop" method is by far the most accurate and has the following advantages: simplicity of equipment and ease of operation; because of the accepted ratio between air and oil, this method may be used to determine the lowest temperature at which autoignition can occur. These conditions ensure a better selection of lubricating materials for operational uses. The results achieved by the "drop" method are in agreement with other reliable parallel methods. ABSTRACT: The process of extraction of Au from selective flotation tailings at the Artemovskaya plant is accompanied by high consumption of cyanide. Investigations were carried out in order to determine how the process of FluoSolids roasting affects the effectiveness of cyanidation of tailings from selective (copper) flotation. Roasting of tailings by the FluoSolids method increases the consumption of cyanide; this is attributable to the fact that along with the decomposition of such active cyanide absorbers as pyrrhotine and its oxidation products, other substances are formed that are detrimental to the cyanidation process. These

pp 184-185

ABSTRACT: From June 11 to 20, 1957, a conference was held in Leningrad on the
laboratory investigation of ores and minerals of rare and trace ele-
ments, called by the All-Union Scientific Research Geological Insti-
tute; during the conference 160 reports from 45 organizations were
heard. In the analytical section reports on the newest chemical and
physico-chemical methods for analysis of rare-metal materials were
discussed together with the review-type reports. Over 30 lectures
were heard in the technological section. VIMS (All-Union Scientific
Research Institute of Mineral Raw Materials), Mekhanobr (Scientific
Research Institute for Mechanical Concentration of Minerals), and the

Card 1/2

SOV/137-59-1-2082

The Seventh Conference on Laboratory Methods for the Investigation of Ores (cont.)

Irkutsk Giredmet (Irkutsk State Scientific Research Institute of Rare Metals) developed methods for flotation concentration of finely dispersed Be ores. The problem on the concentration of spodumene ores was solved (by Mekhanobr and the Irkutsk Giredmet). Giredmet proposed a number of methods for treatment of Zr ores and a method for production of metallic Sr. At the Metallurgical Institute, Academy of Sciences, USSR, methods for extracting Ge from coal ashes were developed. The conference noted that the state of the methods for extraction of rare metals from raw materials, especially the technological processes of complex extraction of rare and dispersed elements are inadequate for the current requirements of the national economy. A serious impediment in the evaluation of the new methods of rare-metal extraction is the complete failure of industrial pilot-plant testing to keep pace with laboratory investigation. Too little attention is paid to the economics of the extraction of rare metals. A proposition was advanced for the creation of a special periodical on rare metals.

TEXT: Experiments were made on the extraction and refining of Zr from operational sulfuric-acid solutions, using the ion-exchange method on ЭДЭ-10 (EDE-10) anionite in Cl-form, and from hydrochloric-acid solutions on КУ-2 (KU-2) grade cationite. On the basis of comparing the results obtained, it is recommended to separate Zr out of hydrochloric acid solutions on KU-2 grade cationite. This method makes it possible to attain rapidly and harmlessly high Zr-extraction out of solutions (98%) and to obtain ZrO₂, free of Fe and Ti(Hf), containing > 98% ZrO₂.

G. Svodtseva

TITLE: A Contribution to the Theory of the Spontaneous Dispersion
of Solid Bodies (K teorii samoproizvol'nego dispergirovaniya
tverdykh tel)

PERIODICAL: Kolloidnyy zhurnal, 1958, Vol XX, Nr 5, pp 655-664 (USSR)

ABSTRACT: The cause for the resistance decrease of a solid in a surface-active medium is the reduction of surface energy on the border solid-medium. Media which are similar in their molecular nature decrease the surface tension of the solid and rupture takes place. For metals, such media are low-melting metals and alloys. Spontaneous dispersion takes place along weakened borders, whereas destruction from outside moves along the plane of greatest stress. The growth of cracks proceeds with increasing speed under outside stress. In spontaneous dispersion, the speed is more uniform, although low. In Figure 2 the left minimum of potential energy corresponds to the stable condition of the particles in the body, the right minimum to the stable condition on the new free surface. In every crystal, there are surface defects and micro-cracks which appear during the growth of the crystal. During spontaneous dispersion the active me-

Card 1/2

SOV-69-20-5-19/23

A Contribution to the Theory of the Spontaneous Dispersion of Solid Bodies

dium penetrates these micro-cracks and enters the interior of the monocrystal. The decrease in resistance in solids is caused by two facts: the decrease of the free surface energy, and the two-dimensional pressure of the adsorbed layer on the steric hindrance at the peak of the crack. Spontaneous dispersion is possible, if the total stress at the top of the micro-crack is greater than the safe stress in the given medium. The safe stress is determined according to a given equation by the surface stress of the body in the medium.

TITLE: Photoelectrical photometry of photospheric granules

PERIODICAL: Referativnyy zhurnal. Astronomiya i Geodeziya, no. 11, 1961, 57,
abstract 11A414 ("Solnechnyye dannyye", 1960 (1961), no. 9, 63-65)

TEXT: The authors describe the results of granule observations by means of the Pulkovo horizontal telescope. The Sun's image shifted, due to diurnal motion, over the membrane of 0.04 mm in diameter (scale was 3".2 in 1 mm). Photometric contours were obtained even for smallest granules, 0".4 in diameter. Recording was made with a Ф3Y-25 (FEU-25) photomultiplier and a d-c amplifier on a MIO-2 (MPO-2) loop oscilloscope. Fluctuations in the brightness of the inter-granular background were discovered by measurements. The "granule-background" brightness difference is equal to 2.1% for granules with half-width 0.42-0".56; 2.6% for granules with half-width 0.70-1".68, and 5.1% for granule groups with dimensions 2.8-5".6. Large fluctuations with an average difference of 8.7% were noted in regions of 30-110" dimensions. There are 8 references.

TITLE: Vertical motion of a rocket in an inhomogeneous gravitational field, taking into account the resistance of the medium

PERIODICAL: Referativnyy zhurnal, Mekhanika, no. 7, 1962, 11, abstract 7A77 (Uch. zap. Mosk. got. ped. in-ta im. V.P. Potemkina. 1960, 86, 77-107) f

TEXT: The authors consider the vertical motion of a rocket from the earth's surface, taking into account the variation of gravitational force according to Newton's law, as well as the air resistance. Integration of the equation of motion

$$M \frac{dV}{dt} = - \frac{dM}{dt} V_r - Mg_0 \left(\frac{R_o}{r} \right)^2 - R$$

Card 1/3

39039

S/124/62/000/007/001/027
D234/D308

Vertical motion of ...

is carried out on the following assumptions: 1) The rectilinear path is divided into three segments, S_1 , S_2 , S_3 ; S_1 being the segment (up to 50 km) where the gravitational force is considered constant, S_2 the segment where the force of resistance is assumed to be equal to 0, on S_3 both the gravitational force and the resistance force are equal to 0; 2) the relative velocity of varying particles V_r is assumed to be constant. For the segment S_1 the authors find a general expression for the velocity of the rocket as a function of time, mass and resistance, and an expression for mass as a function of velocity, time and resistance. These expressions are simplified if one assumes that the rocket moves with uniform acceleration and that the resistance $R = k_1 V^n$. For $R = \frac{1}{2} c_x p_s V^2$ the integration for the segment S_2 is completed in the following cases:
1) c_x and p are equal to their mean values \bar{c}_x , \bar{p} ; 2) $c_x = \bar{c}_x$, $p = p_0 \exp(-\beta s)$; 3) $\bar{c}_x = c_x$, $p = p_0 (1 - s_m/400000)^{49}$. For the segment

Card 2/3

39039

S/124/62/000/007/001/027
D234/D308

Vertical motion of ...

S_2 it is assumed $R = 0$, $P = Mg_0(R_0/r)^2$, $W = a = \text{const}$ and the law of variation of the velocity of the rocket mass is determined. The case when the reactive acceleration is constant, i.e. $a = -(dM/dt) v_r^{M-1} \text{ const}$, is considered next. The law of mass variation, the dependence of the velocity on the path S_2 and that of the path on time are found. For the third segment S_3 with $R = 0$, $P = 0$, a relativistic formula for the velocity of the rocket, generalizing Tsiolkovsiy's formula, is deduced by the method of I. Akeret.

B103/B147

Synthesis of diphenyl-vinyl phosphine...

to diphenyl-chloro phosphine was effected by catalytic disproportionation of the former in the presence of AlCl_3 and constant distilling off of PCl_3 formed. The yield in diphenyl-chloro phosphine was 70%. This method is simple and gives easily reproducible results. Ditolyl-chloro-phosphine was obtained in the same manner (yield 65%). The second synthesis stage was achieved by passing a stream of ethylene oxide through diphenyl-chloro phosphine. The reactivity of the P-Cl bond is reduced owing to the introduction of two phenyl groups into the atom of the trivalent phosphorus. PCl_3 showed the most vigorous reaction with ethylene oxide; whereas phenyl-dichloro phosphine was somewhat less effective. The reaction with diphenyl-chloro phosphine is exothermic. It requires, however, heating at 60°C for 1 hr until it is completed. The third synthesis stage, the isomerization of the β -chloroethyl ester of diphenyl-phosphinous acid to diphenyl- β -chloroethyl phosphine oxide, does not take place smoothly. Different quantities of both the final product mentioned and b): $(\text{C}_6\text{H}_5)_2\text{P}(\text{O})\text{CH}_2\text{CH}_2\text{P}(\text{O})(\text{C}_6\text{H}_5)_2$ are formed depending on the pressure used (atmospheric pressure or vacuum). Ethylene diphosphine derivatives were produced previously (M. I. Kabachnik, Izv. AN SSSR, Otd. khim. n. 1947, 631); the same holds for dioxides (M. I. Kabachnik, T. Ya. Medved', Yu. M.

Polikarpov, Dokl. AN SSSR, 135, 849 (1960)). Isomerization of the β -chloroethyl ester of diphenyl-phosphinous acid yields not only the products mentioned but also (a) owing to spontaneous dehydrochlorination. When the reaction product is treated with alkali, (a) becomes the main product of reaction. The structure of the oxide obtained was checked by its synthesis from the acid chloride of vinyl-phosphinic acid and phenyl magnesium bromide: $\text{CH}_2 = \text{CH} - \text{POCl}_2 + 2\text{C}_6\text{H}_5\text{MgBr} \rightarrow \text{CH}_2 = \text{CH} - \text{P}(\text{O})(\text{C}_6\text{H}_5)_2 + 2\text{MgBrCl}$. SOURCE: AN SSSR, Ural'skiy filial. Institut elektrokhimii. Trudy*, no. 4, 1963. Elektrokhimiya rasplavlennykh solevyykh i tverdykh elektrolitov, 91-95

TOPIC TAGS: refractory oxide, electric ceramic, cerium oxides, CeO_{2-3} , beryllium oxide, alkaline earth magnesium oxide, calcium oxide, strontium oxide, A₂B₄O₇ compound, Sr Ce O₃ mixed oxides, solid solution, electrolysis, oxide electrical conductivity, transport number, transference number

ABSTRACT: The purpose of the work was to verify the recent surmise (Trudy* Institut Elektrokhimii UPAN SSSR, no. 3, Sverdlovsk, 1962, 141) that during electrolysis of the above systems oxygen ions are solely mobile and solid solutions are formed. To achieve this, the transference numbers of the cations involved have been measured. The authors' modified gravimetric method was applied which is described in detail in earlier papers (ib. 149 and DAN SSSR, 1962, 143, 13). The 26 tests were conducted at $1100 \pm 10^\circ$ in an atmosphere of air. A 1.6 v current

ACCESSION NR: AT4008736

was used. The CeO₂ molecular percentage in the samples varied from 50 to 98. The quantity of electricity passed through individual samples varied from 1.41 to 4.266 amp.-hr. To eliminate contingencies, blank tests were made, identically treated minus electrolysis. It was found in all cases that the ionic component of conductivity for all tested combinations of CeO₂-MeO (Me stands for Be, Mg, Ca or Sr) is related to the mobility of oxygen ions. The data obtained confirm an earlier assumption of the formation of solid solutions in the system CeO₂-Me.

tekhn. inform., 1961, 90-91.

TEXT: The proposed method of bright nickel coating uses a usual sulphuric acid electrolyte with a burning-off of the cathode. Ultrasonic irradiation improves the quality of the deposits (mirror luster, resilience and absence of particle inclusions). The ultrasonic irradiation is at a frequency of 20-30 Hz's and a power of 1-3 w./litre. The electrolysis is carried out at a current density of 6-12 A/dm² and a lowered concentration of 1-2 g/litre of the sodium salt of naphthalene disulfide.

Card 1/2

Method of bright nickel coating ...

(isomers 2.0-2.7). The electrolyte contains 200-250 g/liter of nickel in sulphuric acid 20-30 g/liter of sodium chloride 20-30 g/liter of naphthalene disulphonic acid (isomers 1.0-1.5) and the temperature of the electrolyte should be 40-55 °C.

Abstracter's note: Complete translation.
